

Early readability does not reveal where $\pi 0.5$'s action is controlled

Three aligned layer tests on fixed-image counterfactual instructions; each panel retains its own experimental metric.

Probe accuracy measures readability. Cumulative attention-message blocking measures where communication changes. Image K/V swaps measure immediate causal leverage; rollout labels measure behavior. Horizontal segments are measured six-layer interventions; no single-layer K/V sweep was run. R is target-axis progress, not full-vector similarity; the L6-8 profile did not pass the compact-writer gate.
